

# Project Guidelines

First and foremost, this is an opportunity to show off what you have learned. The more different techniques/skills you can demonstrate, the better.

As we discussed (back circa chapter 9), I will evaluate the final product on the following criteria:

- Ambition
  - difficulty/novelty
- User experience
  - functionality
  - ease of intuitive use
  - completeness
- Code quality
  - organization
  - uniformity of style
  - documentation
    - in the code (comments)
    - and for the user (readme)

Though I will naturally ascribe more value to an ambitious project executed successfully, definitely remember that if you have to choose between "simpler and bulletproof" and "really cool but only half-baked and buggy" the former is almost always the way to go.

## Documentation

The user-facing readme should, at minimum, contain:

- any appropriate instructions about how the code should be compiled/run
  - (what keys to press, how to start, how to start over, etc...)
- an overview of how the different classes relate to each other (hints to future developers)
- attention to any sections which seemed particularly subtle or tricky
  - (since these are both the most likely to contain hidden bugs which will require revisiting them, and also the details which benefit most from being very fresh in your mind)

- known issues or limitations
- plans or opportunities for future work/enhancements/extensions

# Submission

Remember the objective here is to provide your classmates with a "release" version of your program.

As a Jack program, it is likely self-contained in its directory, but of course you should include anything that might be needed in order for someone else to get it running. (Hint: you should get a friend to test this for you.)

Please zip up the folder, and submit the zip file here (please don't submit a bunch of individual files).
